

CONIC CONVEX PROGRAMMING AND SELF-DUAL EMBEDDING

Z.-Q. Luo¹ and J.F. Sturm¹ and S. Zhang²

April, 1998

ABSTRACT

How to initialize an algorithm to solve an optimization problem is of great theoretical and practical importance. In the simplex method for linear programming this issue is resolved by either the two-phase approach or using the so-called big M technique. In the interior point method, there is a more elegant way to deal with the initialization problem, viz. the self-dual embedding technique proposed by Ye, Todd and Mizuno [30]. For linear programming this technique makes it possible to identify an optimal solution or conclude the problem to be infeasible/unbounded by solving its embedded self-dual problem. The embedded self-dual problem has a trivial initial solution and has the same structure as the original problem. Hence, it eliminates the need to consider the initialization problem at all. In this paper, we extend this approach to solve general conic convex programming, including semidefinite programming. Since a nonlinear conic convex programming problem may lack the so-called strict complementarity property, it causes difficulties in identifying solutions for the original problem, based on solutions for the embedded self-dual system. We provide numerous examples from semidefinite programming to illustrate various possibilities which have no analogue in the linear programming case.

Key words: Self-duality, conic convex programming, semidefinite programming, initialization, interior point method.

1 Introduction

Like many other optimization methods, interior point methods are iterative in nature. That is, given an interior non-optimal solution, an interior point method would produce a sequence of improving solutions iteratively. Hence, an important question is: How can we get hold of an interior solution to activate the method? A similar question can be asked when one applies the simplex method to solve linear programming problems, because the simplex method assumes the availability of a feasible basic solution to start with. In that case, a common practice is to introduce an auxiliary problem for which a feasible basic solution is known and by solving the auxiliary problem, one can either conclude infeasibility, or indeed obtain a basic feasible solution of the original problem as desired. This is the well-known two-phase approach for the simplex method. A disadvantage of the two-phase approach is that in the feasibility phase, the objective function does not play any role, and consequently the feasible solution obtained may be far from any optimum. A remedy in this respect, is the so-called big M method, which is basically a penalty approach trying to drive the infeasible elements out of the basis as soon as possible. Nevertheless, the big M method works pretty much the same as the two-phase method, since it gives an absolute priority to the feasibility over the objective value.

The situation for the interior point methods is different. Not so long after the regular interior point methods for linear programming received intensive investigation, quest on the initialization issue led to the development of the so-called infeasible interior point methods; see Mizuno [14] for a survey. An infeasible interior point method starts with a possibly infeasible interior solution, and the iterates move towards an optimal solution of the original problem, if it exists, while reducing the feasibility residuals and the duality gap simultaneously. This technique was implemented in the highly successful interior point code OB1 of Lustig, Marsten and Shanno [12, 13] on the Netlib test problems [3]. However, when the original problem is either infeasible or unbounded, then infeasible interior point methods can have difficulty detecting these abnormalities. Later, an alternative, known as *self-dual embedding*, was introduced by Ye, Todd and Mizuno [30]. With the new technique, the original problem is nicely embedded together with its dual problem in a larger system. By solving the embedded system, the original problem is solved completely in the sense that if the problem is solvable, then an optimal solution is provided; if the problem is infeasible, then a Farkas type dual certificate is found; if the problem is unbounded, then an infinite-improving direction is established. So the new technique makes it a lot easier to detect infeasibility; see Xu, Hung and Ye [28]. Moreover, the embedded system has a trivial initial interior feasible solution and its intrinsic size is precisely the same as the original problem. All these nice properties make clear that a usual path-following interior point method, in combination with the self-dual embedding technique, solves linear programming problems satisfactory.

What remained as a point of research was to extend the self-dual embedding technique to solve optimization problems beyond the class of linear programming. Ye [29] showed that indeed the technique is also suitable for monotone LCPs. On one hand, this case is simpler than the linear programming case, since there are only two possible outcomes: either a complementary solution, or a certificate that no such solution exists. In particular, there is no distinction between primal and dual infeasibility. On the other hand, there is a nasty case here that requires two phases, viz. if the set of complementary solutions is unbounded and the so-called q -value is negative. This case cannot occur in linear programming, since the q -value of the associated complementarity systems is then known to be zero.

Another natural extension of linear programming is conic convex programming as discussed by Nesterov and Nemirovski [16]. A very important example of conic programming is semidefinite programming which has been the center of recent research activities in the interior point community. Several groups of authors independently extended the self-dual embedding technique to semidefinite programming, viz. Potra and Sheng [20], De Klerk, Roos and Terlaky [6], Luo, Sturm and Zhang [10] and Nesterov, Todd and Ye [19]. The latter two papers concern the more general case of conic convex programming, each with a different emphasis.

Nesterov, Todd and Ye [19] analyzed the application of logarithmically homogeneous barrier techniques to self-dual embeddings and considered the associated complexity issues. Luo, Sturm and Zhang [10] were concerned with a general duality theory for conic problems and with the question how to determine the status of the original problem from the sequence of iterates solving the self-dual embedding system. Report [10] was lengthy and covered two virtually separate topics. To make our results more accessible, we decide to split the main contents of [10] into two reports. The first one, [11], is completely devoted to duality theory. The second one is the current paper. In this part we will exclusively deal with the self-dual embedding techniques applied to the framework of conic programming. It turns out that a general conic programming problem may have subtle properties that a linear programming problem can never have. For example, it is possible that a conic programming problem with a finite optimal value does not have an attainable optimal solution, or an infeasible problem may become feasible by an infinitesimal change on the problem data. The goal of this paper is to discuss the self-dual embedding technique for conic problems in general, and the detection of the status of a given conic problem by means of solving the self-dual embedding system with a path-following interior point method in particular.

The organization of the paper is as follows. Section 2 presents a general introduction to conic convex programming problems. Sections 3 and 4 discuss schemes of self-dual embedding. Section 5 discusses how a weakly centered sequence can be used to solve a pure self-dual problem. In Section 7, the so-called self-dual embedding technique is discussed extensively. Various examples are given to illustrate how solutions/certificates for the original problem can be deduced from a weakly

centered sequence for the embedded self-dual system. Discussions thus far depend crucially on the availability of a weakly centered sequence. The existence of such a sequence is shown in Section 8. Finally, we conclude the paper in Section 9.

2 Preliminaries

We consider the conic convex program in the following form:

$$(P) \quad p^* = \inf\{c^T x \mid x \in (b + \mathcal{A}) \cap \mathcal{K}\}$$

with its standard dual optimization program

$$(D) \quad d^* = \inf\{b^T z \mid z \in (c + \mathcal{A}^\perp) \cap \mathcal{K}^*\},$$

where $\mathcal{K} \subset \mathfrak{R}^n$ is a convex cone, \mathcal{A} is a linear subspace of \mathfrak{R}^n and b and c are given vectors in \mathcal{A}^\perp and \mathcal{A} respectively. The cone \mathcal{K}^* is the dual cone associated with \mathcal{K} , which is defined as

$$\mathcal{K}^* := \{z \in \mathfrak{R}^n \mid x^T z \geq 0 \forall x \in \mathcal{K}\}.$$

We assume that the convex cone \mathcal{K} is closed, solid ($\text{int } \mathcal{K} \neq \emptyset$) and pointed ($\mathcal{K} \cap -\mathcal{K} = \{0\}$). This assumption obviously holds true for the linear programming case, in which we deal with the nonnegative orthant $\mathcal{K} = \mathcal{K}^* = \mathfrak{R}^n$, and the semidefinite programming case, in which we deal with the cone of positive semidefinite matrices $\mathcal{K} = \mathcal{K}^* = \{X \mid X \succeq 0\}$. We remark that our assumptions on \mathcal{K} imply that the dual cone \mathcal{K}^* is also closed, solid and pointed.

When we solve (P), we intend to find an optimal solution and its optimality certificate if such ones exist, and if not, we shall prove the fact that no optimal solution exists also by a certificate. Solutions of (D) play the role of certificates. For primal optimality a dual optimal solution is a certificate, and for primal infeasibility a Farkas type dual direction is a certificate. Therefore, the primal problem (P) and its dual (D) are closely linked, and are often being solved together. This interpretation of duality is well known for linear programming, and is widely used in various algorithmic approaches.

The homogeneous self-dual model of Goldman and Tucker combines primal solutions and both types of dual solutions in a single model. Unfortunately, the homogeneous self-dual model does not only include certified solutions. In particular, the origin is trivially a solution to any homogeneous self-dual model. So, not all solutions to the homogeneous self-dual model are of interest.

But, if a solution to the homogenous self-dual model is strictly complementary, then it does consist of a certified solution, except for one case. The exceptional case is due to the primal-dual symmetry:

the strictly complementary solution may yield a Farkas–type proof of dual infeasibility, in which case we have still to decide whether the primal is infeasible or unbounded.

The main reason why we can use the nice properties of the self–dual model is that almost all algorithms in the class of interior point methods converge to a strictly complementary solution, provided that such a solution exists. This useful property of interior point methods was made clear in Güler and Ye [5]. Unfortunately, the interior point method cannot be applied directly to the homogeneous self–dual model, since this model admits no interior solutions. Therefore, Ye, Todd and Mizuno [30] embedded the homogeneous self–dual model into an extended self–dual program which has one extra variable and constraint, and a trivial, perfectly centered interior solution.

In this paper we will extend the homogenous self–dual model and its embedding to include the conic programs (P) and (D). Much remains the same as in the linear programming case. Complications arise in the boundary cases. To be specific, we consider (P) for instance. We call (P) infeasible if the set $(b + \mathcal{A}) \cap \mathcal{K}$ is empty. Still, in that case there are two possibilities in general, namely $\text{dist}(b + \mathcal{A}, \mathcal{K}) > 0$ or $\text{dist}(b + \mathcal{A}, \mathcal{K}) = 0$. If $\text{dist}(b + \mathcal{A}, \mathcal{K}) > 0$ we call (P) *strongly infeasible*, and if $\text{dist}(b + \mathcal{A}, \mathcal{K}) = 0$ we call (P) *weakly infeasible*. Remark that weakly infeasibility is impossible in linear programming.

Note that if (P) is weakly infeasible then there exists $x^{(1)}, x^{(2)}, \dots$, such that

$$\text{dist}(x^{(k)}, b + \mathcal{A}) + \text{dist}(x^{(k)}, \mathcal{K}) \rightarrow 0.$$

It is now interesting to introduce the subvalue p^- defined as

$$p^- := \liminf_{\epsilon \downarrow 0} \inf_x \{c^T x \mid \text{dist}(x, b + \mathcal{A}) + \text{dist}(x, \mathcal{K}) < \epsilon\}.$$

If (P) is infeasible then obviously $p^* = \infty$, but the subvalue p^- may be finite (or even $-\infty$) if it is only weakly infeasible. Examples of such phenomena can be found in Section 6.1.

The subvalue p^- is closely related to the dual optimal value d^* in the following way:

$$d^* = \begin{cases} p^- = \infty, & \text{if (D) infeasible and (P) strongly infeasible} \\ -p^-, & \text{otherwise,} \end{cases} \quad (1)$$

(see [11, 23]). Similarly, the dual subvalue d^- can be defined.

General conic duality relation resembles the linear programming case very well if Slater’s condition holds, i.e. if $(b + \mathcal{A}) \cap \text{int } \mathcal{K} \neq \emptyset$. Under Slater’s condition we have

$$p^* = p^- = -d^*. \quad (2)$$

Moreover, if $p^* > -\infty$ then the dual optimum is attained, and the set of dual optimal solutions is bounded.

The above discussed duality provides a means to certify optimality. Farkas–type duality provides a means to certify infeasibility. A Farkas–type dual solution, which we usually call a dual improving direction, is a vector $z \in \mathcal{A}^\perp \cap \mathcal{K}^*$ with $b^\top z < 0$. Such a solution exists if and only if the primal is strongly infeasible.

Notice however that there exists no dual improving direction if (P) is only weakly infeasible. So, how can we certify infeasibility if (P) is only weakly infeasible? For this, we need the concept of a dual improving direction sequence, which is a sequence $z^{(1)}, z^{(2)}, \dots$ such that

$$\limsup_{k \rightarrow \infty} b^\top z^{(k)} < 0, \quad \lim_{k \rightarrow \infty} (\text{dist}(z^{(k)}, \mathcal{A}^\perp) + \text{dist}(z^{(k)}, \mathcal{K}^*)) = 0.$$

Programs that have interior solutions, i.e. $(b + \mathcal{A}) \cap \text{int } \mathcal{K} \neq \emptyset$, are said to be strongly feasible. We have already remarked that if (P) is strongly feasible, then $p^* = p^-$. It is possible to certify that a problem is not strongly feasible, by using yet another type of dual solutions: nonzero dual lower level directions. A nonzero dual lower level direction is by definition a vector $0 \neq z \in \mathcal{A}^\perp \cap \mathcal{K}^*$ such that $b^\top z \leq 0$. Such directions exist if and only if (P) has no interior feasible solutions [11, 23].

For later use, we list here two general rules for dualizing cones. First, for any convex cone $\mathcal{K} \subseteq \mathfrak{R}^n$ and invertible matrix $M \in \mathfrak{R}^{n \times n}$, it holds that

$$(M^\top \mathcal{K})^* = M^{-1} \mathcal{K}^*, \tag{3}$$

see [11, 23]. Second, for two convex cones \mathcal{K}_1 and \mathcal{K}_2 , it holds that

$$\mathcal{K}_1^* \cap \mathcal{K}_2^* = (\mathcal{K}_1 + \mathcal{K}_2)^*. \tag{4}$$

The well known bipolar theorem provides a dual characterization of closed convex cones, viz.

$$\mathcal{K} = \{x \in \mathfrak{R}^n \mid x^\top y \geq 0 \ \forall y \in \mathcal{K}^*\}.$$

Similarly, the interior of a solid convex cone is characterized by

$$\text{int } \mathcal{K} = \{x \in \mathfrak{R}^n \mid x^\top y > 0 \ \forall 0 \neq y \in \mathcal{K}^*\}. \tag{5}$$

3 Self–Duality

Self–duality has been defined by Duffin [2] for conic convex programs that are formulated in the so–called symmetric form. More recently, Ye, Todd and Mizuno [30] formulated a linear program in a different form, and argued that their program is self–dual since “the dual of the problem is equivalent to the primal”. Below, we propose a definition of self–duality that does not depend on the specific form in which the program is formulated.

Definition 1 A conic convex program $CP(b, c, \mathcal{A}, \mathcal{K})$ is Π self-dual if Π is a symmetric permutation matrix such that

$$c = \Pi b, \mathcal{A}^\perp = \Pi \mathcal{A}, \mathcal{K}^* = \Pi \mathcal{K}.$$

If, in addition, $b = c = 0$, then the program is said to be homogeneous.

Notice from the above definition that a self-dual program is indeed its own dual, after a simple reordering of the variables. More precisely, if $CP(b, c, \mathcal{A}, \mathcal{K})$ is a Π self-dual conic convex program, then

$$\Pi(b + \mathcal{A}) = c + \mathcal{A}^\perp, \quad \Pi \mathcal{K} = \mathcal{K}^*,$$

so that $x \in \mathfrak{R}^n$ is primal feasible if and only if Πx is dual feasible, and, using the symmetry of Π ,

$$c^\top = b^\top \Pi,$$

so that the primal objective value $c^\top x$ is identical to the dual objective value $b^\top (\Pi x)$ for all $x \in \mathfrak{R}^n$. Notice also that $\mathcal{K}^* = \Pi \mathcal{K}$ implies that \mathcal{K} is closed; self-dual conic convex programs are therefore always closed.

Remark 1 The requirement that Π is symmetric, i.e. $\Pi = \Pi^\top$, is natural. Namely, for any permutation matrix Π , there holds $\Pi^\top = \Pi^{-1}$. From the relation $\mathcal{A}^\perp = \Pi \mathcal{A}$, it therefore follows using (3) that

$$\Pi \mathcal{A} = \mathcal{A}^\perp = (\Pi^\top \Pi \mathcal{A})^\perp = \Pi^{-1} (\Pi \mathcal{A})^\perp = \Pi^\top \mathcal{A},$$

i.e. $\Pi \mathcal{A} = \Pi^\top \mathcal{A}$ and similarly, $\Pi \mathcal{A}^\perp = \Pi^\top \mathcal{A}^\perp$. Hence, the relation $\mathcal{A}^\perp = \Pi \mathcal{A}$ already implies some symmetry.

Below are two elementary results for self-dual conic convex programs.

Lemma 1 Let \mathcal{A} be a linear subspace of \mathfrak{R}^n such that $\mathcal{A}^\perp = \Pi \mathcal{A}$ for some symmetric permutation matrix Π . Then

$$\Pi P_{\mathcal{A}} = P_{\mathcal{A}^\perp} \Pi, \quad \Pi P_{\mathcal{A}^\perp} = P_{\mathcal{A}} \Pi.$$

Proof. Since Π is a symmetric permutation matrix, we know that $\Pi \mathcal{A}^\perp = \Pi^2 \mathcal{A} = \mathcal{A}$. Hence, the orthogonal decomposition

$$x = y + z, \quad y \in \mathcal{A}, z \in \mathcal{A}^\perp$$

is equivalent to

$$\Pi x = \Pi y + \Pi z, \quad \Pi y \in \mathcal{A}^\perp, \Pi z \in \mathcal{A}.$$

From the above decompositions, it follows for arbitrary x that $\Pi P_{\mathcal{A}}x = \Pi y$ and $P_{\mathcal{A}^\perp} \Pi x = \Pi y$ respectively. \square

Lemma 2 *Let $CP(b, c, \mathcal{A}, \mathcal{K})$ be a Π self-dual program where \mathcal{K} is a solid convex cone. Then*

$$y^T P_{\mathcal{A}} \Pi y = y^T P_{\mathcal{A}^\perp} \Pi y = \frac{1}{2} y^T \Pi y > 0 \text{ for all } y \in \text{int } \mathcal{K}.$$

Proof. Let $y \in \text{int } \mathcal{K}$, then

$$\Pi y \in \Pi \text{ int } \mathcal{K} = \text{int } \Pi \mathcal{K} = \text{int } \mathcal{K}^*,$$

where in the first identity, we used the fact that Π is an invertible matrix. Since \mathcal{K}^* is pointed, and $0 \neq \Pi y \in \text{int } \mathcal{K}^*$, it follows from (5) that

$$0 < y^T \Pi y = y^T \Pi P_{\mathcal{A}} y + y^T \Pi P_{\mathcal{A}^\perp} y.$$

Using now Lemma 1 and the symmetricity of Π , the lemma follows. \square

The properties of self-dual conic convex programs result in a particularly nice form of weak-duality:

Theorem 1 *If $CP(b, c, \mathcal{A}, \mathcal{K})$ is a Π self-dual conic convex program, then*

$$c^T x = \frac{1}{2} x^T \Pi x \geq 0$$

for all $x \in (b + \mathcal{A}) \cap \mathcal{K}$.

Proof. Since $x - b \in \mathcal{A}$, $\Pi x - c \in \mathcal{A}^\perp$ and $b \perp c$, we have

$$0 = (x - b)^T (\Pi x - c) = x^T \Pi x - b^T \Pi x - c^T x = x^T \Pi x - 2c^T x.$$

Moreover, $x^T \Pi x \geq 0$ because $x \in \mathcal{K}$ and $\Pi x \in \mathcal{K}^*$. \square

If x^* is a solution to a Π self-dual program $CP(b, c, \mathcal{A}, \mathcal{K})$ and $(x^*)^T \Pi x^* = 0$, then x^* is called a *self-complementary* solution. It follows from Theorem 1 that if x^* is a self-complementary solution, then it is also an optimal solution.

As before, we denote the optimal value and the subvalue of the conic convex program $CP(b, c, \mathcal{A}, \mathcal{K})$ by p^* and p^- , respectively. That is,

$$p^* := \inf_x \{c^T x \mid x \in (b + \mathcal{A}) \cap \mathcal{K}\}, \quad p^- := \liminf_{\epsilon \downarrow 0} \inf_x \{c^T x \mid x \in \mathcal{K}, \text{ dist}(x, b + \mathcal{A}) < \epsilon\}.$$

If $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$ is self-dual, then

$$p^- = -p^*, \tag{6}$$

as follows from (1). Since $p^* \geq p^-$, we know that the optimal value p^* is nonnegative, and the subvalue p^- is non-positive. This implies in particular that a self-dual program cannot be unbounded.

4 Self-Dual Embedding

There are basically two different types of dual variables involved in closed conic convex programming, viz.

- Dual feasible solutions, and
- Nonzero dual directions.

The former yield lower bounds on the optimal value, and the latter concern the feasibility of the problem. The homogeneous self-dual embedding, to be discussed in Section 4.1, combines both types of dual variables into a single self-dual program. In Section 4.2, we will treat the extended self-dual model, which is a strongly feasible self-dual model for which the optimal solution set corresponds to feasible solutions of the homogeneous self-dual model.

4.1 The Homogeneous Self-Dual Model

Consider a Π_{SD} self-dual program (SD),

$$\text{(SD)} \quad \inf_{x_{\text{SD}}} \{c_{\text{SD}}^T x_{\text{SD}} \mid x_{\text{SD}} \in (b_{\text{SD}} + \mathcal{A}_{\text{SD}}) \cap \mathcal{K}_{\text{SD}}\},$$

i.e. (SD) is the conic convex program $\text{CP}(b_{\text{SD}}, c_{\text{SD}}, \mathcal{A}_{\text{SD}}, \mathcal{K}_{\text{SD}})$. We assume that \mathcal{K}_{SD} is solid. The optimal value of (SD) is denoted by p_{SD}^* . We introduce an invertible matrix $M(b_{\text{SD}}, c_{\text{SD}})$,

$$M(b_{\text{SD}}, c_{\text{SD}}) := \begin{bmatrix} I & b_{\text{SD}} & 0 \\ 0 & 1 & 0 \\ -c_{\text{SD}}^T & 0 & 1 \end{bmatrix},$$

and we let

$$\mathcal{A}_{\text{H}} := M(b_{\text{SD}}, c_{\text{SD}})(\mathcal{A}_{\text{SD}} \times \mathfrak{R} \times \{0\}), \quad \mathcal{K}_{\text{H}} := \mathcal{K}_{\text{SD}} \times \mathfrak{R}_+ \times \mathfrak{R}_+.$$

Applying (3), we have

$$\mathcal{A}_{\text{H}}^\perp = M(b_{\text{SD}}, c_{\text{SD}})^{-T}(\mathcal{A}_{\text{SD}}^\perp \times \{0\} \times \mathfrak{R}),$$

where

$$M(b_{\text{SD}}, c_{\text{SD}})^{-\text{T}} = \begin{bmatrix} I & 0 & c_{\text{SD}} \\ -b_{\text{SD}}^{\text{T}} & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Using the self-duality of (SD), it follows that $\text{CP}(0, 0, \mathcal{A}_{\text{H}}, \mathcal{K}_{\text{H}})$ is a homogeneous Π_{H} self-dual program with

$$\Pi_{\text{H}} = \begin{bmatrix} \Pi_{\text{SD}} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}.$$

This type of homogeneous self-dual program was proposed by Goldman and Tucker [4, 26] in the context of linear programming. The convex cone $\mathcal{A}_{\text{H}} \cap \mathcal{K}_{\text{H}}$ consists of those solutions $(x_{\text{SD}}, x_0, z_0)$ for which

$$(H) \quad \begin{cases} x_{\text{SD}} \in (x_0 b_{\text{SD}} + \mathcal{A}_{\text{SD}}) \cap \mathcal{K}_{\text{SD}}, \\ x_0 \geq 0, \\ z_0 = -c_{\text{SD}}^{\text{T}} x_{\text{SD}} \geq 0. \end{cases}$$

The concepts of complementary solution, improving direction and nonzero lower level direction for (SD) can be characterized in terms of the homogeneous program $(0, 0, \mathcal{A}_{\text{H}}, \mathcal{K}_{\text{H}})$ as follows:

- x_{SD} is a *self-complementary solution* to (SD) if and only if

$$(x_{\text{SD}}, 1, 0) \in \mathcal{A}_{\text{H}} \cap \mathcal{K}_{\text{H}}.$$

- x_{SD} is an *improving direction* for (SD) if and only if

$$(x_{\text{SD}}, 0, z_0) \in \mathcal{A}_{\text{H}} \cap \mathcal{K}_{\text{H}} \text{ for some } z_0 > 0.$$

- x_{SD} is a *nonzero lower level direction* for (SD) if and only if

$$(x_{\text{SD}}, 0, z_0) \in \mathcal{A}_{\text{H}} \cap \mathcal{K}_{\text{H}} \setminus \{0\} \text{ for some } z_0 \geq 0.$$

With the above observation, it is straightforward to prove the following theorem.

Theorem 2 *If $(x_{\text{SD}}, x_0, z_0) \in \mathcal{A}_{\text{H}} \cap \mathcal{K}_{\text{H}}$, then*

$$x_{\text{SD}}^{\text{T}} \Pi_{\text{SD}} x_{\text{SD}} = 0, \quad x_0 z_0 = 0.$$

Moreover, if $(x_{\text{SD}}, x_0, z_0) \in \mathcal{A}_{\text{H}} \cap \mathcal{K}_{\text{H}} \setminus \{0\}$ and (SD) is strongly feasible, then $x_0 > 0$ and x_{SD}/x_0 is a self-complementary solution of (SD).

Remark 2 *It follows from Theorem 2 that if*

$$(x_{SD}, 0, z_0) \in \mathcal{A}_H \cap \mathcal{K}_H \setminus \{0\},$$

then (SD) is not strongly feasible, i.e. it is either weakly feasible, or weakly infeasible, or strongly infeasible. However, if it is strongly infeasible, then it must have an improving direction x'_{SD} and $(x'_{SD}, 0, -c_{SD}^T x'_{SD}) \in \mathcal{A}_H \cap \mathcal{K}_H$.

Remark 3 *Even if (SD) is not strongly feasible, it may have a self-complementary solution x_{SD} , in which case $(x_{SD}, 1, 0) \in \mathcal{A}_H \cap \mathcal{K}_H$.*

4.2 The Extended Self-Dual Model

Given a Π_{SD} self-dual program (SD), we have constructed a Π_H homogeneous self-dual model $(0, 0, \mathcal{A}_H, \mathcal{K}_H)$, generalizing the Goldman–Tucker [4] model to conic convex programming. We will now add a normalization constraint to the model, and we will make the program strongly dual. This results in an extension of Ye, Todd and Mizuno’s self-dual formulation [30] for linear programming, to the context of conic convex programming.

Choose $\iota \in \text{int } \mathcal{K}_H$, and let

$$\rho := \frac{\iota^T P_{\mathcal{A}_H} \Pi_H \iota}{\|P_{\mathcal{A}_H^\perp} \iota\|_2^2}.$$

By construction, \mathcal{K}_H is solid, and we can apply Lemma 2 to conclude that ρ is a well defined positive quantity. Define

$$b_E := \rho P_{\mathcal{A}_H} \Pi_H \iota, \quad c_E := \rho P_{\mathcal{A}_H^\perp} \iota, \quad (7)$$

and notice from Lemma 1 that

$$c_E = \Pi_H b_E. \quad (8)$$

Since c_E is simply a permutation of b_E and $\rho > 0$, we have

$$\|b_E\|_2 = \|c_E\|_2 > 0.$$

Using the definitions of c_E and ρ , and then applying Lemma 2, we further have

$$\frac{\|b_E\|_2^2}{\rho} = \frac{\|c_E\|_2^2}{\rho} = \rho \|P_{\mathcal{A}_H^\perp} \iota\|_2^2 = \iota^T P_{\mathcal{A}_H} \Pi_H \iota = \frac{\iota^T \Pi_H \iota}{2}. \quad (9)$$

We shall now study the conic convex program $\text{CP}(b_E, c_E, \mathcal{A}_E, \mathcal{K}_H)$, where

$$\mathcal{A}_E := (\mathcal{A}_H \cap \text{Ker } b_E^T) + \text{Img } c_E.$$

Just as in the homogeneous self-dual model, we partition the decision variable as

$$x_E = (x_{SD}, x_0, z_0),$$

with $x_{SD} \in \mathcal{K}_{SD}$, $x_0 \in \mathfrak{R}_+$ and $z_0 \in \mathfrak{R}_+$. Introducing an auxiliary variable

$$y_0 := \frac{\rho}{\|c_E\|_2^2} c_E^T x_E, \quad (10)$$

we can reformulate $CP(b_E, c_E, \mathcal{A}_E, \mathcal{K}_H)$ as follows:

$$(E) \quad \begin{aligned} & \min \quad \left(\iota^T \Pi_H \iota / 2 \right) y_0 \\ & s.t. \quad x_E - y_0 \iota \in \mathcal{A}_H \\ & \quad \quad b_E^T x_E = \|b_E\|_2^2 \\ & \quad \quad x_E \in \mathcal{K}_H, y_0 \in \mathfrak{R}. \end{aligned}$$

To see this, remark that by definition of c_E ,

$$x_E - y_0 \iota \in \mathcal{A}_H \iff x_E - \frac{y_0}{\rho} c_E \in \mathcal{A}_H.$$

Since obviously,

$$b_E^T x_E = \|b_E\|_2^2 \iff x_E - b_E \in \text{Ker } b_E^T,$$

we obtain from the above two relations and the fact that $b_E \in \mathcal{A}_H$, $c_E \in \mathcal{A}_H^\perp$, that

$$x_E - b_E \in \mathcal{A}_E \iff \begin{cases} x_E - y_0 \iota \in \mathcal{A}_H, \\ b_E^T x_E = \|b_E\|_2^2 \end{cases}$$

From the relation $x_E \in y_0 \iota + \mathcal{A}_H$, we obtain

$$\iota^T \Pi_H \left(P_{\mathcal{A}_H^\perp} x_E \right) = \iota^T \Pi_H \left(y_0 P_{\mathcal{A}_H^\perp} \iota \right) = \frac{y_0}{2} \iota^T \Pi_H \iota,$$

where we used Lemma 2 in the last identity. Using the definition of b_E , it thus follows that

$$\frac{b_E^T x_E}{\rho} = \iota^T \Pi_H x_E - \frac{y_0}{2} \iota^T \Pi_H \iota.$$

Combining this with (9), we obtain an alternative form for the normalization constraint of (E), viz.

$$b_E^T x_E = \|b_E\|_2^2 \iff \iota^T \Pi_H x_E = \frac{1 + y_0}{2} \iota^T \Pi_H \iota. \quad (11)$$

It is obvious from (11) that the lower level sets of (E) are bounded. Moreover, it is now easily verified that $\iota \in (b_E + \mathcal{A}_E) \cap \text{int } \mathcal{K}_H$, i.e. ι is an interior solution, which can serve as an initial solution in interior point methods (remark that we can choose any $\iota \in \text{int } \mathcal{K}_H$). The feasible solutions x_E of (E) for which $y_0 = 0$ correspond to those solutions of the homogeneous model (H) that are normalized by the constraint $\iota^T \Pi_H x_E = \iota^T \Pi_H \iota / 2$. The normalization guarantees that if $y_0 = 0$, then x_E is a nonzero direction of the homogeneous model (H).

Theorem 3 *The conic convex program $CP(b_E, c_E, \mathcal{A}_E, \mathcal{K}_H)$ has the following properties:*

1. *It is self-dual,*
2. *It has an interior solution, viz. $\iota \in (b_E + \mathcal{A}_E) \cap \text{int } \mathcal{K}_H$, and hence*
3. *It has a self-complementary solution,*
4. *Any self-complementary solution is a nonzero direction of $CP(0, 0, \mathcal{A}_H, \mathcal{K}_H)$, and*
5. *For any nonzero direction x_E of the homogeneous program $CP(0, 0, \mathcal{A}_H, \mathcal{K}_H)$, there exists $\alpha > 0$ such that αx_{SD} is a self-complementary solution for $CP(b_E, c_E, \mathcal{A}_E, \mathcal{K}_H)$.*

Proof.

1. It is already known from (8) that $c_E = \Pi_H b_E$. Moreover, $\mathcal{K}_H^* = \Pi_H \mathcal{K}_H$, since $CP(0, 0, \mathcal{A}_H, \mathcal{K}_H)$ is self-dual. It remains to show that $\mathcal{A}_E^\perp = \Pi_H \mathcal{A}_E$. To this end, we remark using (4) that

$$\begin{aligned}
\mathcal{A}_E^\perp &= \left[(\mathcal{A}_H \cap \text{Ker } b_E^T) + \text{Img } c_E \right]^\perp \\
&= (\mathcal{A}_H \cap \text{Ker } b_E^T)^\perp \cap \text{Ker } c_E^T \\
&= (\mathcal{A}_H^\perp + \text{Img } b_E) \cap \text{Ker } c_E^T \\
&= (\mathcal{A}_H^\perp \cap \text{Ker } c_E^T) + \text{Img } b_E,
\end{aligned}$$

where we used $b_E \perp c_E$ in the last identity. Using (8) and the fact that $\mathcal{A}_H^\perp = \Pi_H \mathcal{A}_H$, it follows that $\mathcal{A}_E^\perp = \Pi_H \mathcal{A}_E$.

2. Using (11), it is easily verified that the solution $x_E = \iota$, $y_0 = 1$ satisfies all the constraints of (E).
3. The self-dual program $CP(b_E, c_E, \mathcal{A}_E, \mathcal{K}_H)$ has a self-complementary solution because it is strongly feasible, see (2).
4. Let x_E be a self-complementary solution of (E). By definition, this means that

$$0 = x_E^T \Pi_H x_E = 2 \|c_E\|_2^2 y_0.$$

Consequently, $y_0 = 0$ and $x_E \in \mathcal{A}_H \cap \mathcal{K}_H$. Moreover, $x_E \neq 0$ due to the normalization constraint (11).

5. Let $x_E \in \mathcal{A}_H \cap \mathcal{K}_H \setminus \{0\}$. Since $\Pi_H \iota \in \text{int } \mathcal{K}_H^*$, we obtain using (5) that

$$\iota^T \Pi_H x_E > 0,$$

so that

$$\frac{\iota^T \Pi_H \iota}{\iota^T \Pi_H x_E} x_E \in \left[b_E + (\mathcal{A}_H \cap \text{Ker } b_E^T) \right] \cap \mathcal{K}_H.$$

□

Remark from Theorem 2 and Theorem 3 that if (SD) is strongly feasible and (x, x_0, z_0) is an optimal solution of (E), then x/x_0 is a self-complementary solution of (SD). Using the interior point method [16], we can thus obtain an optimal solution to (SD) by solving the artificial program (E), for which we can *choose* an initial feasible solution $\iota \in \text{int } \mathcal{K}_{SD}$. We will see in the next section that even if (SD) is not strongly feasible (in which case it may not be solvable), it is still a good idea to solve the embedding (E), if the solution method generates a so-called *weakly centered sequence*.

5 Weakly Centered Sequences

Up to now, we did not use the special structure of the homogeneous program (H) in our study of the extended self-dual program (E). In this section however, we will focus on the full structure of (E), and we partition the decision variable as $x_E = (x_{SD}, x_0, z_0)$, just like we did in the homogeneous model previously. Similarly, we write

$$\iota^T = \left[u_{SD}^T, \quad u_0, \quad v_0 \right].$$

Throughout this section, we make the following assumption:

Assumption 1 *The cone \mathcal{K}_{SD} is solid, i.e. $\text{int } \mathcal{K}_{SD} \neq \emptyset$.*

Since $\iota \in \text{int } \mathcal{K}_H = (\text{int } \mathcal{K}_{SD}) \times \mathfrak{R}_{++} \times \mathfrak{R}_{++}$, there holds

$$u_{SD} \in \text{int } \mathcal{K}_{SD}, \quad u_0 > 0, \quad v_0 > 0.$$

We can now formulate the model (E) as follows:

$$\min \quad (\iota^T \Pi_H \iota / 2) y_0 \tag{12}$$

$$\text{s.t.} \quad x_{SD} - y_0 u_{SD} \in (x_0 - y_0 u_0) b_{SD} + \mathcal{A}_{SD} \tag{12}$$

$$z_0 - y_0 v_0 = -c_{SD}^T (x_{SD} - y_0 u_{SD}) \tag{13}$$

$$\iota^T \Pi_H x_E = (1 + y_0) \iota^T \Pi_H \iota / 2 \tag{14}$$

$$x_{SD} \in \mathcal{K}_{SD}, \quad x_0 \in \mathfrak{R}_+, \quad z_0 \in \mathfrak{R}_+, \quad y_0 \in \mathfrak{R}.$$

Remark from (10) and Theorem 1 that

$$(\iota^T \Pi_H \iota / 2) y_0 = c_E^T x_E = x_0 z_0 + (x^T \Pi_{SD} x) / 2. \quad (15)$$

In the sequel, we will analyze the behavior of weakly centered sequences for (E); the existence of such sequences will be demonstrated in Section 7.

Definition 2 A sequence $x_E^{(k)} = (x_{SD}^{(k)}, x_0^{(k)}, z_0^{(k)}) \in (b_E + \mathcal{A}_E) \cap \mathcal{K}_H$, $k = 1, 2, \dots$, is weakly centered if and only if there exists some constant $\omega \in (0, 1)$ such that

$$x_0^{(k)} z_0^{(k)} \geq \omega c_E^T x_E^{(k)} > 0 \text{ for all } k = 1, 2, \dots, \quad (16)$$

and $\lim_{k \rightarrow \infty} c_E^T x_E^{(k)} = 0$.

Condition (16) is also known as the minimal centrality condition [25]. This condition holds true for all path-following algorithms, and for some potential reduction methods. In particular, Nesterov and Todd [18] developed a framework of primal-dual interior point algorithms for solving self-scaled conic convex programming, which is a subclass of conic convex programming that includes linear programming and semidefinite programming, among others. All their algorithms generate a sequence of weakly centered iterates. We remark here that if (SD) is a linear (semidefinite, self-scaled) programming problem, then (E) is also a linear (semidefinite, self-scaled) programming problem, since $\mathcal{K}_H = \mathcal{K}_{SD} \times \mathfrak{R}_+ \times \mathfrak{R}_+$.

Since $c_E^T x_E = (\iota^T \Pi_H \iota / 2) y_0$, see (9) and (10), it follows by definition that weakly centered sequences satisfy

$$x_0^{(k)} z_0^{(k)} \geq \omega (\iota^T \Pi_H \iota / 2) y_0^{(k)} > 0 \text{ for all } k = 1, 2, \dots$$

This immediately implies the following result.

Lemma 3 Let $x_E^{(1)}, x_E^{(2)}, \dots$ be a weakly centered sequence, then

$$\lim_{k \rightarrow \infty} \frac{y_0^{(k)}}{x_0^{(k)}} = 0 \iff \lim_{k \rightarrow \infty} z_0^{(k)} = 0,$$

and

$$\lim_{k \rightarrow \infty} \frac{y_0^{(k)}}{z_0^{(k)}} = 0 \iff \lim_{k \rightarrow \infty} x_0^{(k)} = 0.$$

The lemma below shows a crucial property of weakly centered sequences: the components $x_0^{(k)}$ and $z_0^{(k)}$ avoid the boundary of the cone \mathfrak{R}_+ essentially as much as possible.

Lemma 4 Let $x_E = (x, x_0, z_0) \in (b_E + \mathcal{A}_E) \cap \mathcal{K}_H$ and $\omega \in (0, 1)$ be such that $x_0 z_0 \geq \omega c_E^T x_E > 0$. For any $x'_E = (x', x'_0, z'_0) \in (b_E + \mathcal{A}_E) \cap \mathcal{K}_H$ there holds

$$x_0 \geq \frac{\omega}{1 + (c_E^T x'_E / c_E^T x_E)} x'_0$$

and

$$z_0 \geq \frac{\omega}{1 + (c_E^T x'_E / c_E^T x_E)} z'_0.$$

Proof. Because $x'_E - x_E \in \mathcal{A}_E$ and $\Pi_H(x'_E - x_E) \in \mathcal{A}_E^\perp$, there holds

$$\begin{aligned} 0 &= (x'_E - x_E)^T \Pi_H(x'_E - x_E) \\ &= (x'_E)^T \Pi_H x'_E + x_E^T \Pi_H x_E - 2x_E^T \Pi_H x'_E \\ &= 2c_E^T(x'_E + x_E) - 2x^T \Pi x' - 2(x_0 z'_0 + z'_0 x_0). \end{aligned} \quad (17)$$

Since $x \in \mathcal{K}$ and $\Pi x' \in \mathcal{K}^*$, we have $x^T \Pi x' \geq 0$. We thus obtain from (17) that

$$c_E^T(x'_E + x_E) \geq x_0 z'_0 + z_0 x'_0 \quad (18)$$

The lemma follows by multiplying (18) with $x_0/c_E^T(x'_E + x_E)$ and $z_0/c_E^T(x'_E + x_E)$ respectively. \square

The argumentation that is used in the proof of Lemma 4 is due to Güler and Ye [5].

Theorem 4 below shows why weakly centered sequences are so interesting in the context of self-dual embeddings. Namely, if we can generate a weakly centered sequence for (E) then we can also solve (SD), whenever it has a complementary solution or an improving direction. In other cases, (SD) must be either weakly feasible or weakly infeasible, and we can generate a sequence of solutions for (SD), for which the amount of constraint violation converges to zero and the corresponding objective values are in the limit contained in the interval $[p_{SD}^-, p_{SD}^*]$.

Theorem 4 Let $x_E^{(k)} = (x^{(k)}, x_0^{(k)}, z_0^{(k)})$, $k = 1, 2, \dots$, be a weakly centered sequence for (E). There holds

1. $\liminf_{k \rightarrow \infty} x_0^{(k)} > 0$ if and only if (SD) has a self-complementary solution. Moreover, if (SD) has a self-complementary solution then $x_{SD}^{(k)}/x_0^{(k)}$, $k = 1, 2, \dots$ is a bounded sequence and therefore it has a cluster point $x_{SD}^{(\infty)}$. Any such cluster point $x_{SD}^{(\infty)}$ is a self-complementary solution of (SD).
2. $\liminf_{k \rightarrow \infty} z_0^{(k)} > 0$ if and only if (SD) is strongly infeasible. Moreover, if (SD) is strongly infeasible, then $x_{SD}^{(k)}/z_0^{(k)}$, $k = 1, 2, \dots$ is a bounded sequence and therefore it has a cluster point $x_{SD}^{(\infty)}$. Any such cluster point $x_{SD}^{(\infty)}$ is an improving direction of (SD).

3. If $\lim_{k \rightarrow \infty} z_0^{(k)} = 0$, then $x_{SD}^{(k)}/x_0^{(k)}$ is a sequence in \mathcal{K}_{SD} for which

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x_{SD}^{(k)}}{x_0^{(k)}}, b_{SD} + \mathcal{A}_{SD}\right) = 0, \quad \lim_{k \rightarrow \infty} \frac{c_{SD}^T x_{SD}^{(k)} + z_0^{(k)}}{x_0^{(k)}} = 0 \leq p_{SD}^*.$$

4. If $\lim_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} = \infty$, then (SD) is infeasible, and $x_{SD}^{(k)}/z_0^{(k)}$ is an improving direction sequence in \mathcal{K}_{SD} , viz.

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x_{SD}^{(k)}}{z_0^{(k)}}, \mathcal{A}_{SD}\right) = 0, \quad \lim_{k \rightarrow \infty} \frac{c_{SD}^T x_{SD}^{(k)}}{z_0^{(k)}} = -1.$$

Proof.

1. Observe from Theorem 3 and the discussion in Section 4.1 we can conclude that (SD) has a self-complementary solution if and only if (E) has an optimal solution $(x_{SD}^*, x_0^*, 0)$ with $x_0^* > 0$. From Lemma 4, we know that if (E) has an optimal solution $(x_{SD}^*, x_0^*, 0)$ with $x_0^* > 0$, then

$$\liminf_{k \rightarrow \infty} x_0^{(k)} \geq \omega x_0^* > 0.$$

The converse is also true, because the sequence $(x_{SD}^{(k)}, x_0^{(k)}, z_0^{(k)})$ is bounded (and hence it has a cluster point, which must be an optimal solution to (E)).

2. Similarly, (SD) is strongly infeasible if and only if the embedding (E) has an optimal solution $(x_{SD}^*, 0, z_0^*)$ with $z_0^* > 0$, which is equivalent with the relation

$$\liminf_{k \rightarrow \infty} z_0^{(k)} \geq \omega z_0^* > 0.$$

3. Suppose that $\lim_{k \rightarrow \infty} z_0^{(k)} = 0$, so that, using Lemma 3,

$$\lim_{k \rightarrow \infty} \frac{y_0^{(k)}}{x_0^{(k)}} = 0.$$

Combining this with (12)-(13), we obtain

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x_{SD}^{(k)}}{x_0^{(k)}}, b_{SD} + \mathcal{A}_{SD}\right) = 0, \quad \lim_{k \rightarrow \infty} \frac{c_{SD}^T x_{SD}^{(k)} + z_0^{(k)}}{x_0^{(k)}} = 0.$$

4. Suppose that $\lim_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} = \infty$. Then $x_0^{(k)} \rightarrow 0$ so that using Lemma 3,

$$\lim_{k \rightarrow \infty} \frac{y_0^{(k)}}{z_0^{(k)}} = 0.$$

Combining this with (12)-(13), we obtain

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x_{\text{SD}}^{(k)}}{z_0^{(k)}}, \mathcal{A}_{\text{SD}}\right) = 0, \quad \lim_{k \rightarrow \infty} \frac{c_{\text{SD}}^{\text{T}} x_{\text{SD}}^{(k)}}{z_0^{(k)}} = -1.$$

By definition, $x_{\text{SD}}^{(k)}/z_0^{(k)}$ is then an improving direction sequence, which implies that (SD) is infeasible (see the discussion on Farkas-type duality in Section 2).

□

Theorem 5 *Let $x_E^{(k)} = (x^{(k)}, x_0^{(k)}, z_0^{(k)})$, $k = 1, 2, \dots$, be a weakly centered sequence for (E). There holds*

$$p_{\text{SD}}^* \geq \limsup_{k \rightarrow \infty} \frac{z_0^{(k)}}{x_0^{(k)}}.$$

Proof. It is known from Theorem 4 that $\liminf_{k \rightarrow \infty} z_0^{(k)} > 0$ if (SD) is strongly infeasible. Using e.g. Lemma 3, it follows that $\liminf_{k \rightarrow \infty} x_0^{(k)} = 0$, and hence

$$p_{\text{SD}}^* = \lim_{k \rightarrow \infty} \frac{z_0^{(k)}}{x_0^{(k)}} = \infty.$$

Now suppose that (SD) is not strongly infeasible, or equivalently, $\liminf_{k \rightarrow \infty} z_0^{(k)} = 0$. For this case, we know from Theorem 4 that $x_{\text{SD}}^{(k)}/x_0^{(k)}$ is a sequence in \mathcal{K}_{SD} , with

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x_{\text{SD}}^{(k)}}{x_0^{(k)}}, b_{\text{SD}} + \mathcal{A}\right) = 0.$$

Therefore, we have the following inequality for the subvalue p_{SD}^- of (SD):

$$p_{\text{SD}}^- \leq \liminf_{k \rightarrow \infty} \frac{c_{\text{SD}}^{\text{T}} x_{\text{SD}}^{(k)}}{x_0^{(k)}} = - \limsup_{k \rightarrow \infty} \frac{z_0^{(k)}}{x_0^{(k)}}.$$

Using (6), the theorem follows. □

Remark 4 *It follows from Theorem 5 that if $\limsup_{k \rightarrow \infty} (z_0^{(k)}/x_0^{(k)}) = \infty$, then (SD) is infeasible.*

Remark 5 *Theorem 5 also shows that if there is no duality gap, i.e. $p_{\text{SD}}^* = 0$, then*

$$\lim_{k \rightarrow \infty} (z_0^{(k)}/x_0^{(k)}) = 0.$$

6 The Primal–Dual Model

Up to now, we have only considered self–dual embeddings for self–dual programs. However, the self–dual embedding technique is applicable to general closed conic convex programs, simply by combining the original primal and dual programs into a single, self–dual program. To be more specific, consider a closed conic convex program $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$, and let

$$b_{\text{SD}} := \begin{bmatrix} b^{\text{T}} & c^{\text{T}} \end{bmatrix}^{\text{T}}, \quad c_{\text{SD}} := \begin{bmatrix} c^{\text{T}} & b^{\text{T}} \end{bmatrix}^{\text{T}}, \quad (19)$$

and

$$\mathcal{A}_{\text{SD}} := \mathcal{A} \times \mathcal{A}^{\perp}, \quad \mathcal{K}_{\text{SD}} := \mathcal{K} \times \mathcal{K}^*. \quad (20)$$

The program (SD) is easily seen to be Π_{SD} self–dual, with

$$\Pi_{\text{SD}} = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix}.$$

If $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$ is both primal and dual feasible, then $(b, c, \mathcal{A}, \mathcal{K})$ and (SD) are equivalent, as follows from the weak duality relation for conic convex programming. Therefore, it is interesting to study the self–dual embedding (E) of the above constructed self–dual model (SD). Since our basic interest lies in the connection with the original program $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$, we partition x_{SD} and u_{SD} as follows:

$$x_{\text{SD}}^{\text{T}} = \begin{bmatrix} x^{\text{T}} & z^{\text{T}} \end{bmatrix}, \quad u_{\text{SD}}^{\text{T}} = \begin{bmatrix} u_p^{\text{T}} & u_d^{\text{T}} \end{bmatrix}.$$

Since (SD) is self–dual, the results of Theorems 4 and 5 are applicable. However, if (SD) has no self–complementary solution, it is not fully equivalent with the original conic convex program $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$. Below, we will therefore use the special structure of the primal–dual model, to deduce as much information as possible for $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$ and its dual.

Theorem 6 *Consider a closed conic convex program $\text{CP}(b, c, \mathcal{A}, \mathcal{K})$ and let $x_E^{(k)}$, $k = 1, 2, \dots$, be a weakly centered sequence for the self–dual embedding (E), where*

$$\text{CP}(b_{\text{SD}}, c_{\text{SD}}, \mathcal{A}_{\text{SD}}, \mathcal{K}_{\text{SD}})$$

is defined as in (19)–(20). Then

1. *(SD) has a self–complementary solution if and only if $\limsup_{k \rightarrow \infty} x_0^{(k)} > 0$.*
2. *(SD) is strongly infeasible if and only if $\limsup_{k \rightarrow \infty} z_0^{(k)} > 0$.*

3. If $\lim_{k \rightarrow \infty} z_0^{(k)} = 0$ then

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x^{(k)}}{x_0^{(k)}}, b + \mathcal{A}\right) = 0, \quad \limsup_{k \rightarrow \infty} \frac{c^T x^{(k)} + z_0^{(k)}}{x_0^{(k)}} \leq p^*$$

and

$$d^* \geq -\liminf_{k \rightarrow \infty} \frac{c^T x^{(k)}}{x_0^{(k)}} \geq -\limsup_{k \rightarrow \infty} \frac{c^T x^{(k)} + z_0^{(k)}}{x_0^{(k)}}.$$

Proof. The cases of self-complementarity and strong infeasibility are known from Theorem 4.

If $\lim_{k \rightarrow \infty} z_0^{(k)} = 0$ then neither (P) nor (D) is strongly infeasible, and it follows from (1) that

$$p^* = -d^-, \quad p^- = -d^*. \quad (21)$$

Moreover, we know from Theorem 4 that

$$\lim_{k \rightarrow \infty} \text{dist}\left(\frac{x^{(k)}}{x_0^{(k)}}, b + \mathcal{A}\right) = 0,$$

so that by definition of the subvalue,

$$p^- \leq \liminf_{k \rightarrow \infty} \frac{c^T x^{(k)}}{x_0^{(k)}}, \quad d^- \leq \liminf_{k \rightarrow \infty} \frac{b^T z^{(k)}}{x_0^{(k)}}. \quad (22)$$

Moreover, using (13) and Lemma 3, it follows that

$$\lim_{k \rightarrow \infty} \frac{c^T x^{(k)} + b^T z^{(k)} + z_0^{(k)}}{x_0^{(k)}} = 0. \quad (23)$$

Combining (21)–(23), the theorem follows. \square

Some remarks concerning Theorem 6 have to be made:

Remark 6 *The case of self-complementarity was already known from Theorem 4, which also states that self-complementarity will be demonstrated by a self-complementary solution, say $x_{SD}^* = (x^*, z^*)$. It is obvious that (x^*, z^*) is then a complementary solution pair for (P) and (D).*

Remark 7 *Similarly, we know from Theorem 4 that strong infeasibility will be demonstrated by an improving direction, say $x_{SD}^* = (x^*, z^*)$. In this case, we have $c^T x^* + b^T z^* < 0$, so that either $c^T x^*$ and $b^T z^*$ are both negative, or exactly one of the quantities $c^T x^*$ and $b^T z^*$ is negative, say $c^T x^* < 0$ and $b^T z^* \geq 0$. In the former case, z^* and x^* demonstrate primal and dual strong infeasibility respectively. In the latter case, it follows that (D) is strongly infeasible, but we do not have complete information about (P): (P) can be either unbounded or infeasible.*

Remark that by definition, (P) is unbounded if and only if $p^* = -\infty$, and (D) is infeasible if and only if $d^* = \infty$. The following is therefore a consequence of Theorem 6.

Corollary 1 *If (P) is unbounded and (D) is weakly infeasible, then*

$$\lim_{k \rightarrow \infty} z_0^{(k)} = 0, \quad \lim_{k \rightarrow \infty} \frac{c^T x^{(k)} + z_0^{(k)}}{x_0^{(k)}} = -\infty.$$

Conversely, if

$$\lim_{k \rightarrow \infty} z_0^{(k)} = 0, \quad \lim_{k \rightarrow \infty} \frac{c^T x^{(k)} + z_0^{(k)}}{x_0^{(k)}} = -\infty, \quad (24)$$

then (D) is weakly infeasible and either (P) is unbounded or $p^ > -d^*$.*

Remark 8 *If (P) is strongly feasible, then $p^* = -d^*$, see (2), and Corollary 1 characterizes the case of primal unboundedness. In general however, we cannot conclude unboundedness from (24), as is illustrated later in this chapter by Example 7.*

There are still some cases that are not described by Theorem 6 and Corollary 1. Namely, it can happen that

- p^* is finite, and $p^* = -d^*$, but (P) is not solvable,
- p^* and d^* are finite, but $p^* + d^* > 0$,
- (P) is weakly feasible, but (D) is weakly infeasible,
- (P) and (D) are both weakly infeasible.

In all these remaining cases, we will obtain some partial information, based on the value of $\limsup_{k \rightarrow \infty} z_0^{(k)} / x_0^{(k)}$.

Theorem 7 *Consider a closed conic convex program $CP(b, c, \mathcal{A}, \mathcal{K})$ and let $x_E^{(k)}$, $k = 1, 2, \dots$, be a weakly centered sequence for the self-dual embedding (E), where we use the primal-dual model $CP(b_{SD}, c_{SD}, \mathcal{A}_{SD}, \mathcal{K}_{SD})$ as defined in (19)–(20). Suppose that $\lim_{k \rightarrow \infty} x_0^{(k)} = \lim_{k \rightarrow \infty} z_0^{(k)} = 0$ and*

$$\liminf_{k \rightarrow \infty} \frac{c^T x^{(k)} + z_0^{(k)}}{x_0^{(k)}} > -\infty, \quad \liminf_{k \rightarrow \infty} \frac{b^T z^{(k)} + z_0^{(k)}}{x_0^{(k)}} > -\infty.$$

Then

1. *If $\limsup_{k \rightarrow \infty} z_0^{(k)} / x_0^{(k)} = \infty$, then (SD) is weakly infeasible, and $p^* \neq -d^*$. Hence, $p^* + d^* = \infty$. Moreover, $x_{SD}^{(k)} / z_0^{(k)}$, $k = 1, 2, \dots$, is an improving direction sequence.*

2. If $0 < \limsup_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} < \infty$, then $p^* \neq -d^*$ and neither (P) nor (D) is strongly feasible. Moreover, $\|x^{(k)}\| > 0$ for all sufficiently large k , and any cluster point of the sequence $x^{(k)}/\|x^{(k)}\|$ is a nonzero lower level direction, demonstrating the fact that (D) is not strongly feasible.

3. If $\limsup_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} = 0$, we have the following:

- If $\lim_{k \rightarrow \infty} \|x^{(k)}\|/x_0^{(k)} = \infty$, then (D) is not strongly feasible. Moreover, $\|x^{(k)}\|$ is positive for all sufficiently large k , and any cluster point of the sequence $x^{(k)}/\|x^{(k)}\|$ is a nonzero lower level direction, demonstrating the fact that (D) is not strongly feasible.
- Otherwise, i.e. if $\liminf_{k \rightarrow \infty} \|x^{(k)}\|/x_0^{(k)} < \infty$, then (P) is solvable and weakly feasible. Moreover, any cluster point of the sequence $x^{(k)}/x_0^{(k)}$ is an optimal solution for (P) and $\liminf_{k \rightarrow \infty} c^T z^{(k)}/x_0^{(k)} = -p^*$.

Proof.

1. It is already known from Theorem 4 that if $\limsup_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} = \infty$, then (SD) is weakly infeasible, and $x_{\text{SD}}^{(k)}/z_0^{(k)}$, $k = 1, 2, \dots$, is an improving direction sequence. Using Corollary 1, we have $p^* > -\infty$ and $d^* > -\infty$, and it follows that $p^* + d^* = \infty$ and $p^* \neq -d^*$.

2. We use that $p^* > -\infty$ and $d^* > -\infty$ to conclude from Theorem 5 that if

$$\limsup_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} > 0,$$

then $p^* + d^* > 0$. Together with (2), this implies that neither (P) nor (D) is strongly feasible. Using Theorem 6, we know that the sequence $x^{(k)}/x_0^{(k)}$ cannot have any cluster point. Namely, if x is such a cluster point then $x \in (b + \mathcal{A}) \cap \mathcal{K}$ and $c^T x < p^*$, a contradiction. Consequently, $\lim_{k \rightarrow \infty} \|x^{(k)}\|/x_0^{(k)} = \infty$ and we obtain from (12) that any cluster point x^* of the sequence $x^{(k)}/\|x^{(k)}\|$ is a nonzero direction, i.e. $0 \neq x^* \in \mathcal{A} \cap \mathcal{K}$. Dividing (13) by x_0 , and using Lemma 3, we have

$$\limsup_{k \rightarrow \infty} \frac{c^T x^{(k)}}{x_0^{(k)}} = -\liminf_{k \rightarrow \infty} \frac{b^T z^{(k)} + z_0^{(k)}}{x_0^{(k)}} < \infty,$$

where the inequality is an assumption of the lemma. Since $x_0^{(k)} = o(\|x^{(k)}\|)$, this inequality implies that $c^T x^* \leq 0$, i.e. x^* is a lower-level direction.

3. Suppose that $\limsup_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} = 0$. The case that $\lim_{k \rightarrow \infty} \|x^{(k)}\|/x_0^{(k)} = \infty$ is completely analogous to the case $0 < \limsup_{k \rightarrow \infty} z_0^{(k)}/x_0^{(k)} < \infty$, which has been treated above.

If $\liminf_{k \rightarrow \infty} \|x^{(k)}\| / x_0^{(k)} < \infty$, then the sequence $x^{(k)} / x_0^{(k)}$ must have a cluster point, and it follows from Theorem 6 that such a cluster point is an optimal solution for (P). We also know from Theorem 6 that there is no complementary solution pair, and hence $\lim_{k \rightarrow \infty} \|z^{(k)}\| / x_0^{(k)} = \infty$. We have already seen above that this implies that any cluster point of $z^{(k)} / \|z^{(k)}\|$ is a dual lower level direction, demonstrating weak feasibility of (P). From (13) and $\limsup_{k \rightarrow \infty} z_0^{(k)} / x_0^{(k)} = 0$, it follows that $\liminf_{k \rightarrow \infty} c^T z^{(k)} / x_0^{(k)} = -p^*$.

□

Solving the self-dual embedding (E) is really equivalent to solving (P) if (P) is strongly feasible, as the following theorem shows.

Theorem 8 *Consider a closed conic convex program $CP(b, c, \mathcal{A}, \mathcal{K})$, and suppose that it is primal strongly feasible. Let $x_E^{(k)}$, $k = 1, 2, \dots$, be a weakly centered sequence for the self-dual embedding (E), where $CP(b_{SD}, c_{SD}, \mathcal{A}_{SD}, \mathcal{K}_{SD})$ is defined as in (19)–(20). Then $CP(b, c, \mathcal{A}, \mathcal{K})$ is*

1. Solvable if and only if

$$\liminf_{k \rightarrow \infty} x_0^{(k)} > 0.$$

Moreover, if (P) is solvable, then any cluster point of the (bounded) sequence

$$\left\{ \left(\frac{x^{(k)}}{x_0^{(k)}}, \frac{z^{(k)}}{x_0^{(k)}} \right) \mid k = 1, 2, \dots \right\},$$

is a complementary solution pair. (Cf. Theorem 6.)

2. Unbounded and dual strongly infeasible if and only if

$$\liminf_{k \rightarrow \infty} z_0^{(k)} > 0.$$

Moreover, if (D) is strongly infeasible then any cluster point of the (bounded) sequence $x^{(1)}, x^{(2)}, \dots$ is a primal improving direction, certifying the dual strong infeasibility. (Cf. Theorem 6 and Remark 7.)

3. Unbounded and dual weakly infeasible if and only if

$$\lim_{k \rightarrow \infty} z_0^{(k)} = 0, \quad \lim_{k \rightarrow \infty} \frac{c^T x^{(k)} + z_0^{(k)}}{x_0^{(k)}} = -\infty. \quad (25)$$

Moreover, if (D) is weakly infeasible then $x^{(k)} / z_0^{(k)}$, $k = 1, 2, \dots$ is a primal improving direction sequence, certifying the dual weak infeasibility. (Cf. Corollary 1.)

4. *Dual weakly feasible and not primal solvable, if and only if*

$$\lim_{k \rightarrow \infty} x_0^{(k)} = 0, \quad \lim_{k \rightarrow \infty} z_0^{(k)} / x_0^{(k)} = 0.$$

Moreover, if (D) is feasible and (P) is not solvable, then

- $z^{(k)} / x_0^{(k)}$, $k = 1, 2, \dots$, is a bounded sequence, and any cluster point of this sequence is a dual optimal solution.
- Any cluster point of the sequence $x^{(k)}$, $k = 1, 2, \dots$ is a nonzero lower level direction, certifying that (D) is not strongly feasible.
- $x^{(k)} / x_0^{(k)}$, $k = 1, 2, \dots$ is a sequence of approximate primal solutions, with

$$\lim_{k \rightarrow \infty} \frac{c^T x^{(k)}}{x_0^{(k)}} = p^*, \quad \lim_{k \rightarrow \infty} \text{dist}\left(\frac{x^{(k)}}{x_0^{(k)}}, b + \mathcal{A}\right) = 0.$$

(Cf. Theorem 7.)

Applying Theorem 6, Corollary 1 and Theorem 7, it is straightforward to prove Theorem 8.

Only slightly weaker results than those of Theorem 8 hold under the condition that $p^* = -d^*$, without requiring primal strong feasibility. Such results are then applicable to Ramana's regularized semidefinite programs [21]. See De Klerk, Roos and Terlaky [7] for a discussion of the self-dual embedding for regularized semidefinite programs.

6.1 Examples in Semidefinite Programming

Several primal-dual interior point algorithms have been extended from linear to semidefinite programming, see [8, 9, 15, 17, 24, 23], among others. All these algorithms generate a sequence of weakly centered iterates, so that all results of Section 6 are applicable.

We will illustrate the theory of weakly centered sequences for (E) with some semidefinite programming problems, i.e. $\mathcal{K} = \mathcal{K}^* = \mathcal{H}_+$. We continue with our convention that given a Hermitian matrix $Y \in \mathcal{H}^{(n)}$, the lower case symbol y denotes $\text{vec}_{\mathbb{H}} Y$, which is the coordinate vector of Y with respect to a fixed orthonormal basis of the real linear space $\mathcal{H}^{(n)}$ of Hermitian $\bar{n} \times \bar{n}$ matrices. Letting n denote the dimension of $\mathcal{H}^{(n)}$, i.e. $n = \bar{n}^2$, it follows that $y \in \mathfrak{R}^n$. The pair of primal and dual semidefinite programming problems is

$$(P) \quad \inf\{C \bullet X \mid X \in (B + \mathcal{A}) \cap \mathcal{H}_+\},$$

and

$$(D) \quad \inf\{B \bullet Z \mid Z \in (C + \mathcal{A}^\perp) \cap \mathcal{H}_+\}.$$

Since $I \in \mathcal{H}_{++}$, we can choose $\iota = \begin{bmatrix} u_p^\top & u_d^\top & u_0^\top & v_0^\top \end{bmatrix}^\top$ as follows:

$$U_p = U_d = I, \quad u_0 = v_0 = 1.$$

With this choice, there holds

$$\frac{\iota^\top \Pi_{\mathbb{H}} \iota}{2} = \bar{n} + 1.$$

We obtain the following formulation of the extended self-dual model (E) from (12)–(14), by specializing it to semidefinite programming.

$$\begin{aligned} \min \quad & (\bar{n} + 1)y_0 \\ \text{s.t.} \quad & X - y_0 I \in (x_0 - y_0)B + \mathcal{A} \\ & Z - y_0 I \in (x_0 - y_0)C + \mathcal{A}^\perp \\ & z_0 - y_0 = -C \bullet (X - y_0 I) - B \bullet (Z - y_0 I) \\ & \text{tr } X + \text{tr } Z + x_0 + z_0 = (1 + y_0)(\bar{n} + 1) \\ & X \succeq 0, Z \succeq 0, x_0 \geq 0, z_0 \geq 0, y_0 \in \mathfrak{R}. \end{aligned}$$

Weakly centered sequences will now be parameterized by a continuous parameter $\epsilon > 0$ such that

$$\lim_{\epsilon \downarrow 0} y_0(\epsilon) = 0.$$

We will only discuss those difficult cases where $\lim_{\epsilon \downarrow 0} (x_0(\epsilon) + z_0(\epsilon)) = 0$.

First, we consider a weakly infeasible problem.

Example 1 (Weakly infeasible) *Let $\bar{n} = 2$ and*

$$B = \begin{bmatrix} 0 & 1 \\ & 0 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & 0 \\ & 1 \end{bmatrix}, \quad \mathcal{A} = \left\{ X \mid X = \begin{bmatrix} 0 & 0 \\ & x_{22} \end{bmatrix} \right\}.$$

The primal is weakly infeasible,

$$p^* = \inf \left\{ x_{22} \mid X = \begin{bmatrix} 0 & 1 \\ & x_{22} \end{bmatrix} \succeq 0 \right\} = \infty$$

and the dual is strongly feasible and unbounded,

$$d^* = \inf \left\{ 2z_{12} \mid Z = \begin{bmatrix} z_{11} & z_{12} \\ & 1 \end{bmatrix} \succeq 0 \right\} = -\infty.$$

We construct a weakly centered sequence for $0 < \epsilon \leq 1/3$ as follows:

$$X(\epsilon) = \epsilon^3 I + \begin{bmatrix} 0 & \epsilon^2 \\ & \epsilon \end{bmatrix}, \quad Z(\epsilon) = \epsilon^3 I + \begin{bmatrix} 3 - (2\epsilon + 2\epsilon^2 + 3\epsilon^3) & -\epsilon \\ & \epsilon^2 \end{bmatrix},$$

Figure 1: Example 1

Figure 2: Example 2

$$y_0(\epsilon) = \epsilon^3, \quad x_0(\epsilon) = \epsilon^2 + \epsilon^3, \quad z_0(\epsilon) = \epsilon + \epsilon^3.$$

We see that

$$\lim_{\epsilon \downarrow 0} z_0(\epsilon) = 0, \quad \lim_{\epsilon \downarrow 0} \frac{B \bullet Z(\epsilon) + z_0(\epsilon)}{x_0(\epsilon)} = -\infty,$$

which indeed implies that the dual is unbounded and the primal is weakly infeasible, see Theorem 8. Finally, notice that

$$\lim_{\epsilon \downarrow 0} \frac{z_0(\epsilon)}{x_0(\epsilon)} = \infty.$$

In order to be able to solve the self-dual embedding (E), we specialized the predictor-corrector algorithm for semidefinite programming (with Nesterov-Todd type primal-dual directions [18, 17, 24]) to the special structure of (E). The plots below show the numerical results for the examples in this section. The solid lines represent the primal objective values

$$\frac{C \bullet X^{(k)}}{x_0^{(k)} - y_0^{(k)}}, \quad \frac{C \bullet X^{(k)} + z_0^{(k)}}{x_0^{(k)} - y_0^{(k)}},$$

whereas the dual objective values

$$\frac{B \bullet Z^{(k)}}{x_0^{(k)} - y_0^{(k)}}, \quad \frac{B \bullet Z^{(k)} + z_0^{(k)}}{x_0^{(k)} - y_0^{(k)}}$$

are represented by dashed lines. Recall from Theorem 6 that in the limit, $(C \bullet X^{(k)} + z_0^{(k)}) / (x_0^{(k)} - y_0^{(k)})$ and $(B \bullet Z^{(k)} + z_0^{(k)}) / (x_0^{(k)} - y_0^{(k)})$ provide lower bounds on p^* and d^* respectively.

The next example, which is from Vandenberghe and Boyd [27], gives a feasible problem, where strong duality fails to hold.

Example 2 (Weakly dual) Let $\bar{n} = 3$ and

$$B = \begin{bmatrix} 0 & 1/3 & 0 \\ & 0 & 0 \\ & & 1/3 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & -1/3 & 0 \\ & 0 & 0 \\ & & 2/3 \end{bmatrix},$$

$$\mathcal{A} = \left\{ X \mid X = \begin{bmatrix} x_{11} & -x_{33}/2 & x_{13} \\ & 0 & x_{23} \\ & & x_{33} \end{bmatrix} \right\},$$

so that the primal is solvable and weakly feasible,

$$p^* = \inf \left\{ \frac{2}{3}x_{33} - \frac{2}{3}x_{12} \mid X = \begin{bmatrix} x_{11} & (1-x_{33})/2 & x_{13} \\ & 0 & x_{23} \\ & & x_{33} \end{bmatrix} \succeq 0 \right\} = \frac{2}{3}$$

and the dual is also solvable and weakly feasible,

$$d^* = \inf \left\{ \frac{1}{3}z_{33} + \frac{2}{3}z_{12} \mid Z = \begin{bmatrix} 0 & z_{33} - 1 & 0 \\ & z_{22} & 0 \\ & & z_{33} \end{bmatrix} \succeq 0 \right\} = \frac{1}{3}.$$

Remark that $p^* + d^* = 1 > 0$ so that strong duality fails. A weakly centered sequence for $0 < \epsilon \leq 1/2$ is given by

$$X(\epsilon) = \epsilon^2 I + \begin{bmatrix} 1 & \epsilon/2 & 0 \\ & 0 & 0 \\ & & 0 \end{bmatrix}, \quad Z(\epsilon) = \epsilon^2 I + \begin{bmatrix} 0 & -\epsilon & 0 \\ & 3 - (2\epsilon + 4\epsilon^2) & 0 \\ & & 0 \end{bmatrix},$$

$$y_0(\epsilon) = \epsilon^2, \quad x_0(\epsilon) = \epsilon + \epsilon^2, \quad z_0(\epsilon) = \epsilon + \epsilon^2$$

so that

$$\lim_{\epsilon \downarrow 0} \frac{z_0(\epsilon)}{x_0(\epsilon)} = 1,$$

which indeed implies that $p^* \neq -d^*$, see Theorem 7.

The third case is a problem where strong duality holds, but there exists no complementary solution pair (see Vandenberghe and Boyd [27]).

Example 3 (Strongly dual) Let $\bar{n} = 2$ and

$$B = \begin{bmatrix} 0 & 0 \\ & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & 1 \\ & 0 \end{bmatrix}, \quad \mathcal{A} = \left\{ X \mid X = \begin{bmatrix} 0 & x_{12} \\ & 0 \end{bmatrix} \right\},$$

Figure 3: Example 3

Figure 4: Example 4

so that the primal is solvable and weakly feasible,

$$p^* = \inf \left\{ 2x_{12} \mid X = \begin{bmatrix} 0 & x_{12} \\ & 1 \end{bmatrix} \succeq 0 \right\} = 0$$

and the dual is strongly feasible but not solvable,

$$d^* = \inf \left\{ z_{22} \mid Z = \begin{bmatrix} z_{11} & 1 \\ & z_{22} \end{bmatrix} \succeq 0 \right\} = 0.$$

Notice that $p^* + d^* = 0$, but the dual has no optimal solution. A weakly centered sequence for $0 < \epsilon \leq 1/3$ is

$$X(\epsilon) = \epsilon^3 I + \begin{bmatrix} 0 & -\epsilon^2 \\ & \epsilon \end{bmatrix}, \quad Z(\epsilon) = \epsilon^3 I + \begin{bmatrix} 3 - (2\epsilon + 3\epsilon^2 + 3\epsilon^3) & \epsilon \\ & \epsilon^2 \end{bmatrix},$$

$$y_0(\epsilon) = \epsilon^3, \quad x_0(\epsilon) = \epsilon + \epsilon^3, \quad z_0(\epsilon) = 2\epsilon^2 + \epsilon^3.$$

Hence,

$$\lim_{\epsilon \downarrow 0} x_0(\epsilon) = 0, \quad \lim_{\epsilon \downarrow 0} \frac{z_0(\epsilon)}{x_0(\epsilon)} = 0,$$

which indeed holds if and only if the primal is weakly feasible and the dual is not solvable, see Theorem 8.

So far, we have seen a weakly infeasible problem with $\lim_{\epsilon \downarrow 0} z_0(\epsilon)/x_0(\epsilon) = \infty$, a feasible problem with only weak duality and $\lim_{\epsilon \downarrow 0} z_0(\epsilon)/x_0(\epsilon) \in (0, \infty)$ and a strongly dual problem with

$\lim_{\epsilon \downarrow 0} z_0(\epsilon)/x_0(\epsilon) = 0$. The reader may wonder whether the asymptotic behavior of the indicator $z_0(\epsilon)/x_0(\epsilon)$ completely characterizes the three cases that we consider. Unfortunately, this is not the case, as the next example shows.

Example 4 (Weakly infeasible) *Let $\bar{n} = 2$, and consider*

$$B = \begin{bmatrix} 0 & 1 \\ & 0 \end{bmatrix}, \quad C = 0, \quad \mathcal{A} = \left\{ X \mid X = \begin{bmatrix} 0 & 0 \\ & x_{22} \end{bmatrix} \succeq 0 \right\}.$$

The primal is weakly infeasible,

$$p^* = \inf \left\{ 0 \mid X = \begin{bmatrix} 0 & 1 \\ & x_{22} \end{bmatrix} \succeq 0 \right\} = \infty,$$

and the dual is solvable and weakly feasible,

$$d^* = \inf \left\{ 2z_{12} \mid Z = \begin{bmatrix} z_{11} & z_{12} \\ & 0 \end{bmatrix} \succeq 0 \right\} = 0.$$

We construct a weakly centered sequence for $0 < \epsilon \leq 1/3$ as

$$X(\epsilon) = \epsilon^2 I + \begin{bmatrix} 0 & \epsilon \\ & 1 \end{bmatrix}, \quad Z(\epsilon) = \epsilon^2 I + \begin{bmatrix} 2 - 3(\epsilon + \epsilon^2) & -\epsilon \\ & 0 \end{bmatrix},$$

$$y_0(\epsilon) = \epsilon^2, \quad x_0(\epsilon) = \epsilon + \epsilon^2, \quad z_0(\epsilon) = 2\epsilon + \epsilon^2.$$

We see that

$$\lim_{\epsilon \downarrow 0} \frac{z_0(\epsilon)}{x_0(\epsilon)} = 2.$$

The reader may still wonder whether we can distinguish weak infeasibility from strong duality. It appears somewhat difficult indeed, to construct an example of an infeasible problem where $z_0(\epsilon)/x_0(\epsilon) \rightarrow 0$, but it does exist.

Example 5 (Weakly infeasible) *Let $\bar{n} = 3$ and*

$$B = 0, \quad C = \begin{bmatrix} 0 & -1 & 0 \\ & 0 & 0 \\ & & 0 \end{bmatrix}, \quad \mathcal{A} = \left\{ X \mid X = \begin{bmatrix} x_{11} & x_{12} & x_{13} \\ & 0 & -x_{11}/2 \\ & & x_{33} \end{bmatrix} \right\}.$$

The primal is solvable and weakly feasible,

$$p^* = \inf \left\{ -2x_{12} \mid X = \begin{bmatrix} x_{11} & x_{12} & x_{13} \\ & 0 & -x_{11}/2 \\ & & x_{33} \end{bmatrix} \succeq 0 \right\} = 0$$

Figure 5: Example 5

Figure 6: Example 6

and the dual is weakly infeasible,

$$d^* = \inf \left\{ 0 \mid Z = \begin{bmatrix} z_{11} & -1 & 0 \\ & z_{22} & z_{11} \\ & & 0 \end{bmatrix} \succeq 0 \right\} = \infty.$$

We construct a weakly centered sequence for $0 < \epsilon \leq 1/3$ by

$$X(\epsilon) = \epsilon^4 I + \begin{bmatrix} \epsilon^2 & \epsilon^3/2 & 0 \\ & 0 & -\epsilon^2/2 \\ & & 1 \end{bmatrix},$$

$$Z(\epsilon) = \epsilon^4 I + \begin{bmatrix} \epsilon^2 & & -\epsilon & 0 \\ & 3 - (\epsilon + 2\epsilon^2 + \epsilon^3 + 4\epsilon^4) & \epsilon^2 & \\ & & & 0 \end{bmatrix},$$

$$y_0(\epsilon) = \epsilon^4, \quad x_0(\epsilon) = \epsilon + \epsilon^4, \quad z_0(\epsilon) = \epsilon^3 + \epsilon^4,$$

so that

$$\lim_{\epsilon \downarrow 0} \frac{z_0(\epsilon)}{x_0(\epsilon)} = 0.$$

After Example 5 there is little hope that feasibility with lack of strong duality would imply $\limsup_{\epsilon \downarrow 0} z_0(\epsilon)/x_0(\epsilon) > 0$. Indeed, we can construct a feasible problem with only weak duality but $\lim_{\epsilon \downarrow 0} z_0(\epsilon)/x_0(\epsilon) = 0$.

Example 6 (Weakly dual) Let $\bar{n} = 4$ and

$$B = \begin{bmatrix} 0 & 1/3 & 0 & 0 \\ & 0 & 0 & 0 \\ & & 0 & 0 \\ & & & 1/3 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & -1/3 & 0 & 0 \\ & 0 & 0 & 0 \\ & & 0 & 0 \\ & & & 2/3 \end{bmatrix},$$

$$\mathcal{A} = \left\{ X \mid X = \begin{bmatrix} x_{11} & -x_{44}/2 & x_{13} & x_{14} \\ & 0 & -x_{11}/2 & x_{24} \\ & & x_{33} & x_{34} \\ & & & x_{44} \end{bmatrix} \right\}.$$

The primal is solvable and weakly feasible,

$$p^* = \inf \left\{ \frac{2}{3}x_{44} - \frac{2}{3}x_{12} \mid X = \begin{bmatrix} x_{11} & (1-x_{44})/2 & x_{13} & x_{14} \\ & 0 & -x_{11}/2 & x_{24} \\ & & x_{33} & x_{34} \\ & & & x_{44} \end{bmatrix} \succeq 0 \right\} = \frac{2}{3},$$

and the dual is also solvable and weakly feasible,

$$d^* = \inf \left\{ \frac{2}{3}z_{12} + \frac{1}{3}z_{44} \mid Z = \begin{bmatrix} z_{11} & z_{44} - 1 & 0 & 0 \\ & z_{22} & z_{11} & 0 \\ & & 0 & 0 \\ & & & z_{44} \end{bmatrix} \succeq 0 \right\} = \frac{1}{3}.$$

Hence, $p^* + d^* = 1 > 0$, so that strong duality fails. Remark that the first three rows and columns of this program are the same as in Example 5, with the additional constraints

$$x_{12} = \frac{1-x_{44}}{2} \leq \frac{1}{2}, \quad z_{12} = z_{44} - 1 \geq -1.$$

As a consequence, we can construct a weakly centered sequence that is very similar to the one in Example 5, viz.

$$X(\epsilon) = \epsilon^4 I + \begin{bmatrix} \epsilon^2 & \epsilon^3/2 & 0 & 0 \\ & 0 & -\epsilon^2/2 & 0 \\ & & 1 & 0 \\ & & & \epsilon - \epsilon^3 \end{bmatrix},$$

$$Z(\epsilon) = \epsilon^4 I + \begin{bmatrix} \epsilon^2 & & 0 & 0 \\ & -\epsilon & \epsilon^2 & 0 \\ & 4 - (2\epsilon + 2\epsilon^2 + 5\epsilon^4) & 0 & 0 \\ & & 0 & 0 \\ & & & 0 \end{bmatrix},$$

Figure 7: Example 7

Notice however, that $d^- = 0$. We construct a weakly centered sequence for small ϵ by

$$X(\epsilon) = \epsilon^{12}I + \begin{bmatrix} \epsilon^6 & -\epsilon^3/2 & 0 & & \\ & 3 - O(\epsilon^3) & \epsilon^6 & & \\ & & \epsilon^{12} & & \\ & & & \epsilon^7 & -\epsilon^5 \\ & & & & \epsilon^3 \end{bmatrix},$$

$$Z(\epsilon) = \epsilon^{12}I + \begin{bmatrix} \epsilon^6 & \epsilon^9 & 0 & & \\ & \epsilon^{12} & -\epsilon^6/2 & & \\ & & 3 - O(\epsilon^3) & & \\ & & & \epsilon^5 & \epsilon^7 \\ & & & & \epsilon^9 \end{bmatrix},$$

$$y_0(\epsilon) = \epsilon^{12}, \quad x_0(\epsilon) = \epsilon^7 + \epsilon^{12}, \quad z_0(\epsilon) = \epsilon^5 + \epsilon^{12}.$$

We have

$$\lim_{\epsilon \downarrow 0} \frac{c^T x(\epsilon) + z_0(\epsilon)}{x_0(\epsilon)} = \frac{-2\epsilon^5 + \epsilon^5 + \epsilon^{12}}{\epsilon^7 + \epsilon^{12}} = -\infty,$$

but (P) is not unbounded. See Corollary 1 and Remark 8.

7 Existence of Weakly Centered Sequences

In this section, we will prove the existence of a weakly centered sequence for (E), if we use the primal-dual model $CP(b_{SD}, c_{SD}, \mathcal{A}_{SD}, \mathcal{K}_{SD})$ of Section 6. In fact, we will give a constructive proof

using the theory of logarithmically homogeneous barriers, which has been developed by Nesterov and Nemirovsky [16].

Definition 3 *Let \mathcal{K} be a closed, solid and pointed convex cone. Then $F : \text{int } \mathcal{K} \rightarrow \Re$ is a ν -logarithmically homogeneous barrier for \mathcal{K} if F is a twice continuously differentiable convex function on $\text{int } \mathcal{K}$ such that $F(x^{(i)}) \rightarrow \infty$ for any sequence $x^{(i)}$ in $\text{int } \mathcal{K}$, $i = 1, 2, \dots$, that converges to the boundary of \mathcal{K} , and*

$$F(tx) = F(x) - \nu \log t \text{ for all } x \in \text{int } \mathcal{K}, t > 0, \quad (26)$$

where $\nu \geq 1$ is a fixed parameter.

It is known that any closed, pointed and solid convex cone \mathcal{K} is endowed with a logarithmically homogeneous barrier, see Theorem 2.5.1 in [16]. Moreover, Proposition 2.3.5 in [16] states that logarithmically homogeneous barriers are strictly convex functions. Important special cases are the n -logarithmically homogeneous barrier $F(x) = -\sum_{i=1}^n \log x_i$ for the cone $\mathcal{K} = \Re_+^n$, and the n -logarithmically homogeneous barrier $F(X) = -\log \det X$ for the cone $\mathcal{K} = \mathcal{H}_+^{(n)}$.

Let $F(x)$ be a ν -logarithmically homogeneous barrier for \mathcal{K} , and define its conjugate (or Legendre–Young–Fenchel transform) by

$$F^*(z) := \sup_{x \in \text{int } \mathcal{K}} \{(-z)^\top x - F(x)\}. \quad (27)$$

Notice that if $z \notin \mathcal{K}^*$, then $(-z)^\top x > 0$ for some $x \in \text{int } \mathcal{K}$, which together with (26) implies $F^*(z) = \infty$. In fact, Nesterov and Nemirovsky [16] showed that $F^*(z)$ is a ν -logarithmically homogeneous barrier for \mathcal{K}^* (see Theorem 2.4.4 therein). Hence, $F^*(z) < \infty$ if and only if $z \in \text{int } \mathcal{K}^*$. Moreover, the biconjugate F^{**} of F is again F , i.e. $F(x) = F^{**}(x)$, see e.g. Rockafellar [22].

Let $x \in \text{int } \mathcal{K}$. Using definition (27) and the first order optimality conditions for concave maximization, it follows that

$$F^*(z) = (-z)^\top x - F(x) \text{ if } z = -\nabla F(x),$$

from which we obtain

$$-\nabla F(x) \in \text{int } \mathcal{K}^*, \quad (28)$$

and

$$\nabla F^*(z) = -x \text{ if } z = -\nabla F(x). \quad (29)$$

Using (26), it is straightforward to show that

$$\nabla F(x/t) = t \nabla F(x) \text{ for all } t > 0, \quad (30)$$

and

$$\nabla F(x)^\top x = -\nu. \quad (31)$$

The above properties of F are also listed by Nesterov and Todd [17] and Nesterov, Todd and Ye [19]. Based on the barrier F , one can define a *barrier path* with parameter $\mu > 0$, see Theorem 9 below. In the case of semidefinite programming, the central path is the barrier path for $F(x) = -\log(\det X)$.

Theorem 9 (barrier path) *Let \mathcal{K} be a convex cone that is closed, pointed and solid. Suppose that $CP(b, c, \mathcal{A}, \mathcal{K})$ is a conic convex program that is primal and dual strongly feasible. Let $F : \text{int } \mathcal{K} \rightarrow \Re$ be a ν -logarithmically homogeneous barrier for \mathcal{K} , and define*

$$\phi_\mu(x) := (-c)^T x - \mu F(x),$$

with $\mu > 0$. Then there exists a unique vector $x(\mu) \in (b + \mathcal{A}) \cap \text{int } \mathcal{K}$ such that

$$\phi_\mu(x(\mu)) = \max\{\phi_\mu(x) \mid x \in (b + \mathcal{A}) \cap \text{int } \mathcal{K}\}.$$

Moreover, letting $z(\mu) := -\mu \nabla F(x(\mu))$, there holds

$$x(\mu)^T z(\mu) = \nu \mu, \quad x(\mu) = -\mu \nabla F^*(z(\mu)),$$

and

$$z(\mu) = \arg \max\{(-b)^T z - \mu F^*(z) \mid z \in (c + \mathcal{A}^\perp) \cap \text{int } \mathcal{K}^*\}.$$

Proof. First, notice that $\phi_\mu(\cdot)$ is a concave function. Moreover, for all $x \in (b + \mathcal{A}) \cap \text{int } \mathcal{K}$ and $z \in (c + \mathcal{A}^\perp) \cap \text{int } \mathcal{K}^*$, there holds

$$\phi_\mu(x) = b^T z - z^T x - \mu F(x) \leq b^T z + \mu F^*(z/\mu).$$

Hence, $\phi_\mu(x)$ is bounded from above on $(b + \mathcal{A}) \cap \text{int } \mathcal{K}$, and since $\phi_\mu(\cdot)$ is a strictly concave function, it follows that $\phi_\mu(\cdot)$ achieves a maximum, and the maximizer $x(\mu)$ is unique. From the first-order optimality conditions, we know that $x(\mu)$ satisfies

$$\nabla \phi_\mu(x(\mu)) = -c - \mu \nabla F(x(\mu)) \in \mathcal{A}^\perp.$$

Letting $z(\mu) := -\mu \nabla F(x(\mu))$, it follows from (28) that $z(\mu) \in (c + \mathcal{A}^\perp) \cap \text{int } \mathcal{K}^*$, and using (29)–(30), we have

$$x(\mu) = -\nabla F^*(z(\mu)/\mu) = -\mu \nabla F^*(z(\mu)),$$

so that

$$-b - \mu \nabla F^*(z(\mu)) \in \mathcal{A}.$$

The above relation shows that $z(\mu)$ satisfies the optimality conditions for

$$\max\{(-b)^T z - \mu F^*(z) \mid z \in (c + \mathcal{A}^\perp) \cap \text{int } \mathcal{K}^*\}.$$

Finally, it follows from (31) that

$$z(\mu)^\top x(\mu) = -\mu \nabla F(x(\mu))^\top x(\mu) = \nu \mu.$$

□

We now propose the following barrier for $\mathcal{K} \times \mathcal{K}^*$,

$$F_{\text{SD}}(x, z) := F(x) + F^*(z).$$

Using (26), we see that $F_{\text{SD}}(x, z)$ is a 2ν -logarithmically homogeneous barrier, and from definition (27) and the fact that $F(x) = F^{**}(x)$, we obtain that

$$F_{\text{SD}}^*(z, x) = F_{\text{SD}}(x, z).$$

This leads to the following definition:

Definition 4 *Let \mathcal{K} be a solid convex cone such that $\mathcal{K}^* = \Pi\mathcal{K}$ for some symmetric permutation matrix Π . A ν -logarithmically homogeneous barrier $F : \text{int } \mathcal{K} \rightarrow \Re$ for \mathcal{K} is Π self-conjugate if and only if*

$$F^*(\Pi x) = F(x) \text{ for all } x \in \text{int } \mathcal{K}.$$

For the extended self-dual model (E), we define

$$F_{\text{E}}(x_{\text{SD}}, x_0, z_0) := F_{\text{SD}}(x_{\text{SD}}) - \log x_0 - \log z_0,$$

where F_{SD} is a (2ν) -logarithmically homogeneous Π_{SD} self-conjugate barrier for \mathcal{K}_{SD} . It is easy to verify that F_{E} is then a $(2\nu+2)$ -logarithmically homogeneous Π_{H} self-conjugate barrier for \mathcal{K}_{H} . Since (E) is strongly feasible (see Theorem 3), we can apply Theorem 9 to arrive at the following result.

Theorem 10 *Define*

$$\phi_\mu(x_{\text{E}}) := (-c_{\text{E}})^T x - \mu F_{\text{E}}(x_{\text{E}}),$$

and let

$$x_{\text{E}}(\mu) := \arg \max\{\phi_\mu(x_{\text{E}}) \mid x_{\text{E}} \in (b_{\text{E}} + \mathcal{A}_{\text{E}}) \cap \text{int } \mathcal{K}_{\text{E}}\}.$$

Then

$$x_0(\mu)z_0(\mu) = \mu = \frac{1}{\nu + 1} c_{\text{E}}^T x_{\text{E}}(\mu)$$

and $\lim_{\mu \downarrow 0} c_{\text{E}}^T x_{\text{E}}(\mu) = 0$.

Proof. From Theorem 9, we know that $x_E(\mu)$ is well defined, and

$$x_E(\mu)^\top z_E(\mu) = 2(\nu + 1)\mu, \quad x_E(\mu) = -\mu \nabla F_E^*(z_E(\mu)),$$

where $z_E(\mu) := -\mu \nabla F_E(x_E(\mu))$. In addition, Theorem 9 tells us that $z_E(\mu)$ is the maximizer of the function $-b_E^\top z_E - \mu F_E^*(z_E) = \phi_\mu(\Pi_H z_E)$ over all dual interior solutions z_E , and therefore

$$x_E(\mu) = \Pi_H z_E(\mu) = -\mu \Pi_H \nabla F_E(x_E(\mu)). \quad (32)$$

Noticing that

$$\nabla F_E(x_E) = \left[\nabla F_{\text{SD}}(x_{\text{SD}})^\top, \quad -1/x_0, \quad -1/z_0 \right]^\top,$$

we obtain from (32) that

$$x_0(\mu) = \mu/z_0(\mu).$$

Hence,

$$x_0(\mu)z_0(\mu) = \mu = \frac{1}{2(\nu + 1)} x_E(\mu)^\top z_E(\mu) = \frac{1}{\nu + 1} c_E^\top x_E(\mu),$$

where we used Theorem 1. □

Theorem 10 shows that $\{x_E(\mu) \mid \mu > 0\}$ is a weakly centered sequence for (E).

We have used the theory of logarithmically homogeneous barriers, to establish the existence of weakly centered sequences for conic convex programming. In the special case of semidefinite programming however, there is no need for this barrier argument. Namely, consider the primal–dual path–following methods such as treated in e.g. [8, 9, 15, 17, 24, 23]. We may initialize these methods with a primal–dual pair $(x_E^{(0)}, z_E^{(0)})$ that satisfies $z_E^{(0)} = \Pi_H x_E^{(0)}$, i.e. the initial primal and dual solutions are essentially the same. In particular, we may start with the identity solution, as explained in Section 6.1. It is then easily checked that all subsequent iterates $(x_E^{(k)}, z_E^{(k)})$ also satisfy such a property. Namely, primal–dual path–following algorithms generate iterates in a so-called $\mathcal{N}_\infty^-(\beta)$ –neighborhood of the central path,

which by definition implies that

$$x_0^{(k)} z_0^{(k)} \geq (1 - \beta) \frac{(x_E^{(k)})^\top z_E^{(k)}}{2n + 2}.$$

This shows that iterative sequences in the $\mathcal{N}_\infty^-(\beta)$ –neighborhood are weakly centered with $\omega = (1 - \beta)/(n + 1)$.

8 Conclusions

In this paper, we addressed questions such as how to solve a general conic convex program and certify the solution(s) obtained. It turned out that a conic convex program can be in one or more of the following states: 1) It is solvable; 2) It is weakly infeasible; 3) It is strongly infeasible; 4) It is weakly feasible; and 5) It is strongly feasible. Certificates verifying a given state involve the dual solutions. To get a complete picture about the problem, we need to solve a primal–dual embedded system, for which we studied relevant properties. As a natural next step, we showed how the self–dual embedding technique [30] for linear programming can be extended to this general case. By a central path following method, we further proved that a weakly centered sequence for the self–dual embedding system will be generated, which indeed provides much information about the solution to the original problem. By various examples from semidefinite programming, we demonstrated several intricate cases which can never occur in linear programming. We conclude from this study that solving a general conic convex program requires substantially more effort and care than solving a classical linear programming problem. Nevertheless, it is also clear from our study that the self–dual embedding technique and the path–following methodology provide good tools for solving conic convex programming problems, as long as an easy computable self–concordant barrier of the cone is available.

We remark that similar techniques can be used to deal with the strict feasibility problem:

$$\text{Find } x \in (b + \mathcal{A}) \cap \text{int } \mathcal{K}. \quad (33)$$

This includes the problem of finding a matrix satisfying a set of matrix inequalities strictly; such problems arise in stability analysis for linear differential inclusions [1]. If we use an algorithm that produces a maximally complementary solution, such as the path–following algorithm for semidefinite programming [6], then the self–dual embedding technique can be applied directly on (P) with $c = 0$, to solve the strict feasibility problem. But if the algorithm generates merely weakly centered sequences, then we should apply the embedding technique to the following, auxiliary problem:

$$\text{Find } x, t \text{ such that } x - \iota \in \mathcal{K} \text{ and } x - tb \in \mathcal{A},$$

where ι is a given vector in the interior of \mathcal{K} . If (33) has a solution, then it is even possible to find it in finite time (in the real number computational model). Otherwise, i.e. if (33) has no solution, then we obtain in the limit a certificate z satisfying

$$\iota^T z < 0, b^T z = 0, z \in \mathcal{A}^\perp \cap \mathcal{K}^*,$$

which indeed demonstrates infeasibility of (33).
